

9/p₁

DESCRIPTION

A Gene Encoding Novel Human Secretory Type Phospholipase A₂5 Technical Field

This invention relates to a human secretory type phospholipase A₂; a DNA encoding the protein; an expression vector having the DNA; a transformant having the vector; a method for producing the protein by using the transformant; an antibody recognizing the protein; a screening method for
10 a compound by using the protein; and a compound obtained by the screening method.

Background Art

Phospholipase A₂ (PLA₂; EC 3.1.1.4) is a general term of phospholipids-
15 cleaving enzyme that hydrolyzes the 2-acyl ester bond of 3-sn-phosphoglyceride. PLA₂ is involved in the digestion of phospholipids in food and the generation and metabolism of phospholipids in the cell membranes. In addition, PLA₂ plays as a rate-limiting enzyme of the arachidonic acid cascade in the production of lipid mediators including prostaglandins. It
20 has been known that various types of PLA₂s exist in mammals. PLA₂s are classified into 4 different families, such as the secretory PLA₂, cytosolic PLA₂, Ca²⁺-independent PLA₂, and platelet-activating factor-acetylhydrolase, based on the localization, Ca²⁺ requirement, and substrate specificity (Balsinde et al., J. Biol. Chem. 272, 16069-16072 (1997)).

25 Among them, secretory PLA₂ family comprises PLA₂ enzymes that are secreted into the outside of the cells and have a relatively low molecular weight (13,000 - 15,000). As the member of the family, 5 types including

IB type, IIA type, IIC type, V type, and X type, have been already identified. Each molecule has 12 to 16 Cys residues that form disulfide-bonds in the molecule, and possesses a consensus active site consisting of His-Asp residues. In addition, the molecules have a common Ca^{2+} binding region.

5 Micro mole order of Ca^{2+} concentration is required for the exertion of the enzyme activity (Tischfield et al., J. Biol. Chem., 272, 17247-17250 (1997), Cupillard et al., J. Biol. Chem., 272, 15745-15752 (1997)).

It is assumed that IB type has a function as a digestive enzyme in the pancreas etc. and is involved in the progression of inflammation, such as
10 endotoxin shock, through the binding to its specific receptor. It is also assumed that IIA type plays a role in various inflammatory responses because this type is expressed in blood platelets and synovial cells etc., and its expression is elevated during stimulation of inflammatory cytokines. However, the inflammatory response is normal in genetically IIA-deficient
15 mice. Thus, its pathological significance remains unresolved. V type is expressed in the heat and several inflammatory cells. X type is expressed in the tissues related to the immunity such as spleen and thymus. Although it is suggested that both types are involved in the bio-regulation and inflammatory response, their importance in the body has not been clearly
20 identified (Hanasaki et al., Cell Technology, 17, 694-701 (1998)).

Disclosure of Invention

The object of this invention is to provide a novel type of human secretory phospholipase A_2 ; a DNA encoding the protein of this invention;
25 a vector comprising the DNA of this invention; a transformant having the vector of this invention; a method for producing human secretory type phospholipase A_2 by using the transformant of this invention; an antibody

specifically recognizing the protein of this invention; a screening method of a compound by using the protein of this invention; and a compound obtained from the screening method.

In the process of intensive studies regarding the physiological
5 function of mouse X type PLA₂, the inventors have found the presence of partial sequence with homology to mouse X type PLA₂ in Expressed Sequence Tags (EST) database. Based on the partial sequence, they have found a DNA sequence encoding novel secretory type PLA₂ protein from mouse spleen cDNA library. Further, the inventors have found out a DNA sequence encoding
10 human secretory type PLA₂ protein (IIE type) from human spleen cDNA library, to accomplish this invention.

The invention relates to:

(1) A protein which comprises an amino acid sequence from first Asn
15 to 123rd Cys of that shown in SEQ ID No.:30;

(2) The protein as described in above (1) which comprises an amino acid sequence from -19th Met to 123rd Cys of that shown in SEQ ID No.:30;

(3) A protein which comprises the amino acid sequence of above (1) or (2), in which one or more amino acid residues are substituted, deleted,
20 inserted, or added, and has a phospholipase A₂ activity;

(4) A DNA which encodes the protein as described in any one of above (1), (2) and (3);

(5) The DNA as described in above (4) which comprises a base sequence from 116th A to 484th C of that shown in SEQ ID No.:29;

25 (6) The DNA as described in above (5) which comprises a base sequence from 59th A to 484th C of that shown in SEQ ID No.29;

(7) A DNA which hybridizes to the DNA as described in above (5) or (6)

under the stringent condition and encodes the protein having a phospholipase A₂ activity;

(8) An expression vector which has the DNA as described in any one of above (4) to (7);

5 (9) A transformant which is obtained by inserting the expression vector as described in above (8) to a host;

(10) The transformant as described in above (9) wherein the host is a mammalian cell line;

(11) A method for producing a protein which comprises a step for
10 culturing the transformant as described in above (9) or (10), and a step of recovering the protein as described in any one of above (1), (2) and (3) from the culture;

(12) An antibody which specifically recognizes the protein as described in any one of above (1), (2) and (3);

15 (13) A diagnostic agent for secretory type phospholipase A₂-related diseases, which comprises the antibody as described in above (12);

(14) An assay kit for secretory type phospholipase A₂, which comprises the antibody as described in above (12);

(15) A therapeutic agent for secretory type phospholipase A₂-related
20 diseases, which comprises the antibody as described in above (12);

(16) A screening method of a compound specifically inhibiting a secretory type phospholipase A₂ activity which uses the protein as described in any one of above (1), (2) and (3); and

(17) A composition for use as a IIE type phospholipase A₂ inhibitor
25 containing, as an effective ingredient, a compound of the formula (I):

wherein A ring is an optionally substituted carbocycle, or an optionally substituted heterocycle;

R¹ is -COOH, -SO₃H, or -PO(OH)₂;

5 R² is -COCONH₂, -CH₂CONH₂, or -CH₂CONHNH₂;

n is an integer of 0 to 6,

which is obtained by the screening method as described in above (16); and

(18) The composition as described in above (17) wherein the IIE type phospholipase A₂ is the protein as described in any one of above (1), (2)
10 and (3).

The protein of this invention is "A protein which comprises an amino acid sequence from first Asn to 123rd Cys of that shown in SEQ ID No.:30". Preferable is "A protein which comprises an amino acid sequence from -20th
15 Met to 123rd Cys of that shown in SEQ ID No.:30". "A protein which comprises an amino acid sequence from first Asn to 123rd Cys of that shown in SEQ ID No.:30" means a mature protein. "A protein which comprises an amino acid sequence from -20th Met to 123rd Cys of that shown in SEQ ID No.:30" is an immature protein that has a signal peptide. The protein of this invention
20 also includes "A protein which comprises the amino acid sequence as described above (1) or (2), in which one or more amino acid residues are substituted, deleted, inserted, or added, and has a secretory type phospholipase A₂ activity". Number or site of "substitution, deletion, insertion, addition of amino acid residue" is not limited, if the modified protein has the same
25 activity as the protein consisting of the amino acid sequence shown in SEQ

ID No.:30. In this invention, "phospholipase A₂ activity" means "phospholipid-cleaving activity that hydrolyzes 2-acyl ester bond of 3-sn-phosphoglyceride in a Ca²⁺-dependent manner".

Although these mutations in the amino acid sequences can be caused naturally by mutation or modification after transcription, artificial
5 modification can also be caused by the DNA of this invention. The protein of this invention includes all proteins which are encoded by modified DNA and have the characteristics as mentioned above regardless of the cause or mean of these modification/mutation.

10 The DNA of this invention means "a DNA encoding the protein of this invention". As the DNA of this invention, a DNA which encodes the mature protein and comprises a base sequence from 116th A to 484th C of that shown in SEQ ID No.:29 is preferably given for example. More preferably, a DNA
15 which encodes the immature protein and comprises a base sequence from 59th A to 484th C of that shown in SEQ ID No.:29 is given for example. A DNA that hybridizes to the DNA of this invention under the stringent condition and encodes the protein having a secretory type phospholipase A₂ activity is also included in the DNA of this invention. "A DNA that hybridizes to
20 the DNA of this invention under the stringent condition" can be obtained by using the DNA of the encoding region as a probe. "Hybridize under the stringent condition" means that positive hybridizing signal can be observed after heating at 42°C in 6×SSC, 0.5% SDS and 50% formamide solution and washing 68°C in 0.1×SSC, 0.5% SDS solution.

25 Using the DNA of this invention, a production of the recombinant protein can be performed based on textbooks and references such as Molecular

Cloning etc. More concretely, a transcription initiation codon is added at upper stream of the DNA to be expressed, and a transcription stop codon is added at down stream of the DNA. A regulator gene such as a promoter sequence (Ex. Trp, lac, T7, SV40 initial promoter) which controls
5 transcription is also added. The expression plasmid, which can replicate and work in the host cells, is prepared by insertion of the DNA into an appropriate vector (ex. PBR322, pUC19, pSV-SPORT1 etc.).

The transformant is obtained by insertion of the expression vector into host cells. As a host cell, procaryotes such as E. coli, monocellular
10 eukaryotes such as yeast, and cells derived from multicellular organisms such as insects and mammals are given for examples. Mammal's cells are preferable. As a mammal's cell, CHO cell, 293 cell, COS-7 cell are given for example.

The antibody of this invention is an antibody against the polypeptide of this invention or peptide fragment that can compose the epitope, and
15 includes both of polyclonal antibodies and monoclonal antibodies. Secretory type PLA₂ is involved in the release of fatty acids (ex. arachidonic acid). Excess release of fatty acids cause various diseases such as septic shock, adult respiratory distress syndrome, pancreatitis, bronchial asthma, allergic rhinitis, rheumatoid arthritis, etc. It is possible to diagnose
20 these diseases by the evaluation of a concentration of secretory type phospholipase A₂. The antibody of this invention provides a diagnostic agent and an assay kit for secretory type phospholipase A₂-related diseases. If the antibody inhibits a PLA₂ activity, the antibody itself can be a therapeutic agent for the diseases caused by PLA₂.

25 The invention relates to a composition for use as IIE type phospholipase A₂ activity inhibitor which containing a compound obtained by the screening method of this invention. The compound has a structural feature shown in

following formula (I).

wherein A ring is optionally substituted carbocycle, or optionally substituted heterocycle;

5 R^1 is $-\text{COOH}$, $-\text{SO}_3\text{H}$, or $-\text{PO}(\text{OH})_2$;

R^2 is $-\text{COCONH}_2$, $-\text{CH}_2\text{CONH}_2$, or $-\text{CH}_2\text{CONHNH}_2$;

n is an integer of 0 to 6.

The term "carbocycle" used in this specification means a ring derived
10 from a saturated or unsaturated, substituted or unsubstituted 5 to 14
membered, preferably 5 to 10 membered, and more preferably 5 to 7 membered
organic nucleus whose ring forming atoms (other than hydrogen atoms) are
solely carbon atoms. A ring comprising two to three of the carbocycle is
also included in the above-mentioned ring. An example of the carbocycle
15 includes cycloalkane (such as cyclopropane, cyclobutane, cyclopentane,
cyclohexane, cycloheptane, and cyclooctane), cycloalkene (cyclobutene,
cyclopentene, cyclohexene, cycloheptene, and cyclooptene), benzene,
naphthalene, indene, phenanthrene, anthracene and the like.

The term "heterocycle" used in this specification means a ring derived
20 from monocyclic or polycyclic, saturated or unsaturated, substituted or
unsubstituted heterocyclic nucleus having 5 to 14 ring atoms and containing
1 to 3 hetero atoms selected from the group consisting of nitrogen, oxygen
and sulfur atom. An example of the heterocycle includes thiophene,
thianthrene, furan, pyran, benzofuran, isobenzofuran, chromene, xanthene,
25 phenoxthine, pyrrole, imidazoly, pyrazoly, thiazoly, isothiazoly, oxazoly,

isoxazoly, pyridine, pyrazine, pyrimidine, pyridazine, triazine, indolizine, isoindole, indole, indazole, purine, quinolizine, isoquinoline, quinoline, phthalazine, naphthyridine, quinoxaline, quinazoline, cinnoline, pteridine, carbazole, phenanthridine, acridine, perimidine, phenazine, phenothiazine, phenoxazine, pyrrolo [1,2-a] pyrazine, pyrrolo[1,2-b] pyridazine, pyrrolotriazine and the like.

An example of substituents for "optionally substituted carbocycle", "optionally substituted heterocycle" includes alkyl, haloalkyl, alkenyl, alkynyl, carboxy, halogen (F, Cl, Br, I), hydroxyalkyl, hydroxy, nitro, cyano, mercapto, thioformyl, thioacetyl, thiocarboxy, dithiocarboxy, thiocarbamoyl, sulfinio, sulfo, sulfamoyl, sulfoamino, optionally substituted aryl, optionally substituted aralkyl, optionally substituted heteroaryl, optionally substituted heteroarylalkyl and the like. These substituents can be substituted at any one to four arbitrary position of consisting atoms on the above-mentioned carbocycle and heterocycle.

The term "alkyl" means a C1 - C8 straight or branched chain alkyl, or a C3 - C8 cyclic chain alkyl. An example of the alkyl includes methyl, ethyl, n-propyl, isopropyl, n-butyl, isobutyl, tert-butyl, n-pentyl, isopentyl, n-hexyl, n-heptyl, n-octyl, cyclopropyl, cyclobutyl, cyclopentyl, cyclohexyl, cycloheptyl and the like.

The term "haloalkyl" means a C1 - C8 straight or branched chain haloalkyl, or a C3 - C8 cyclic chain haloalkyl substituted by at least one halogen. An example of the haloalkyl includes chloromethyl, fluoromethyl, trifluoromethyl, 2,2,2-trifluoroethyl, 1,1-difluoroethyl, trichloromethyl, 2,2,2-trichloroethyl, 1,1-dichloroethyl and the like.

The term "alkenyl" means a C2 - C8 straight or branched chain alkenyl, or a C3 - C8 cyclic chain alkenyl having at least one double bond. An example

of the alkenyl includes vinyl, 1-propenyl, 2-propenyl, isopropenyl, 2-cyclobutene-1-yl, 2-cyclopentene-1-yl, 3-cyclopentene-1-yl, 2-cyclohexene-1-yl and the like.

The term "alkynyl" means a C2 - C8 straight or branched chain alkynyl, or a C3 - C8 cyclic chain alkynyl having at least one triple bond. An example of the alkynyl includes ethynyl, 1-propynyl, 2-propynyl, 1-butyne, 2-butyne, 3-butyne and the like.

The term "halogen" means fluorine, chlorine, bromine and iodine.

The term "aryl" means a C6 - C14 aromatic mono ring or aromatic condensed ring. An example of the aryl includes phenyl, naphthyl (such as 1-naphthyl, 2-naphthyl), anthryl (such as 1-anthryl, 2-anthryl, 3-anthryl) and the like.

The term "aralkyl" means a group wherein the aforementioned "alkyl" is substituted with the above-mentioned "aryl". Such aryl may have a bond at any substitutable position. An example of the aralkyl includes benzyl, phenylethyl (such as 2-phenylmethyl), phenylpropyl (such as 3-phenylpropyl), naphthylethyl (such as 1-naphthylethyl, 2-naphthylethyl), anthrylmethyl (such as 9-anthrylmethyl) and the like. Particularly, benzyl and phenylethyl are preferred.

The term "heteroaryl" means a 5 to 6 membered aromatic ring which contains one or more hetero atoms selected from the group consisting of oxygen, sulfur and nitrogen atoms.

The term "heteroaralkyl" includes a group wherein the aforementioned "alkyl" is substituted with the above-mentioned "heteroaryl". Such heteroaryl may have a bond at any substitutable position. An example of the heteroaralkyl includes thienylmethyl (such as 2-thienylmethyl), thienylethyl (such as 2-(thiophene-2-yl)ethyl), furylmethyl (2-furylmethyl), furylethyl (such as 2-(furan-2-yl)ethyl), pyrrolylmethyl

(such as 2-pyrrolylmethyl), pyrrolylethyl (such as 2-pyrrole-2-yl)ethyl), imidazolylmethyl (such as 2-imidazolylmethyl, 4-imidazolylmethyl), imidazolyethyl (such as 2-(imidazole-2-yl)ethyl), pyrazolylmethyl (such as 3-pyrazolylmethyl), pyrazolyethyl (such as 2-(pyrazole-3-yl)ethyl),
5 thiazolylmethyl (such as 2-thiazolylmethyl), thiazolyethyl (such as 2-(thiazole-2-yl)ethyl), isothiazolylmethyl (such as 3-isothiazolylmethyl), isoxazolylmethyl (such as 3-isoxazolylmethyl), oxazolylmethyl (such as 2-oxazolylmethyl), oxazolyethyl (such as 2-(oxazole-2-yl)ethyl), pyridylmethyl (such as 2-pyridylmethyl, 3-pyridylmethyl, 4-pyridylmethyl),
10 pyridylethyl (such as 2-pyridylethyl) and the like..

An example of substituents for "optionally substituted heteroaryl" and "optionally substituted heteroarylalkyl" includes alkyl, haloalkyl, alkenyl, alkynyl, carboxy, halogen (F, Cl, Br, I), hydroxyalkyl, hydroxy, nitro, cyano, mercapto, thioformyl, thioacetyl, thiocarboxy, dithiocarboxy,
15 thiocarbamoyl, sulfinio, sulfo, sulfamoyl, sulfoamino and the like.

Brief Description of Drawings

Figure 1 shows a positional relationship of oligomers of SEQ ID No.:2, 3, 4, and 5.

20 Figure 2 shows the PLA₂ activities of the Lysate and Supernatant of the transformants. One of the transformants has the gene encoding human secretory type PLA₂ of this invention. The other transformant does not have the PLA₂ gene.

Figure 3 shows the Ca²⁺ dependence for PLA₂ activity in the supernatant
25 of the transformant having the gene encoding the human PLA₂ of this invention.

Figure 4 shows the inhibiting activities for secretory type PLA₂ including the human PLA₂ of this invention by Indoxam.

Best Mode for Carrying Out the Invention

This invention mainly relates to a novel human secretory type phospholipase A₂.

5 Explained below are a preparation method for the protein of this invention, a preparation method for the antibody, and a screening method for the compound which inhibits the phospholipase A₂ activity as below. Unless otherwise mentioned, for example, gene recombinant, production methods for a recombinant protein using animal cells, insect cells, yeast and E. coli, 10 separation and purification methods for the expressed protein, analysis method, immunological means, technologies well-known in this field, can be used to this invention.

The DNA sequence encoding the secretory type PLA₂ of this invention

15 The DNA of this invention can be produced or obtained based on the sequence information described in this invention by general gene engineering-technique (Molecular Cloning 2d Ed, Cold Spring Harbor Lab. Press (1989) so on). More specifically, cDNA library is prepared by conventional methods from appropriate sources expressing the DNA of this 20 invention, and the DNA clone is selected from the library using specific probes or antibodies (Proc. Natl. Acad. Sci., USA., 78, 6613 (1981); Science, 22, 778 (1983) so on). Examples of the cDNA source are cells and tissues that express the DNA of this invention or cultured cells derived from these cells or tissues. Separation of total RNA, separation and purification of 25 mRNA, obtaining cDNA and it's cloning can be performed by conventional methods. The commercially available cDNA libraries such as Clontech library can also be used.

The screening method for the DNA of this invention from the library is not limited, and can be performed by conventional methods. Available methods are as follows: an immunological screening for the corresponding cDNA clone using a specific antibody for the protein encoded by the cDNA, a plaque hybridization using a probe that selectively binds to the objective DNA, a colony hybridization and so on and combination of these methods. DNA Probes used in these methods are chemically synthesized based on the information of the DNA sequence or a fragment of the obtained DNA of this invention. Also sense/antisense primers designed from the information of the sequence can be used for cloning probes.

DNA/RNA amplification by PCR method (Science, 230, 1350 (1985)) can suitably be used for obtaining the DNA of this invention. If it is difficult to obtain the full length cDNA from the library, various methods such as RACE (Rapid amplification of cDNA ends; : Experimental Medicine, 12(6), 35 (1988)) can be supplemented. The primers used for the PCR method can be designed based on the sequence information of the DNA clarified by this invention. Such primers can be synthesized by conventional methods. Isolation and purification of the amplified DNA/RNA fragments can also be performed with conventional method described above. For example, it can be performed by gel electrophoresis etc. The DNA or various fragments obtained at the above methods can be sequenced by dideoxy method (Proc. Natl. Acad. Sci., USA., 74, 5463 (1977)), Maxam and Gilbert method (Methods in Enzymology, 65, 499 (1980)) or by using a sequencing kit etc.

Hereafter, the DNA cloning method of this invention is described.

(1) Sequence determination of the DNA encoding the mouse secretory type PLA₂

A sequence determination method for the DNA fragment encoding mouse secretory type PLA₂ which corresponds to human secretory type PLA₂ of this invention is described below. Finding out a sequence homologous to mouse X type PLA₂ is firstly done. Next step is preparing primers on the basis of the sequence. And finally, PCR is performed using cDNA library originated mouse spleen as a template. By sequencing the obtained DNA fragment, the DNA fragment encoding mouse secretory type PLA₂ can be determined.

10 (A) Isolation of a novel PLA₂ cDNA fragment and analysis of expression pattern in mouse tissues

In order to analyze the gene from which a DNA fragment is originated and function of a protein encoded by the gene, it is necessary to isolate cDNAs which connect to 5' terminus and 3' terminus of this fragment and to
15 confirm the sequence integrity. For this purpose, it is advantageous to use tissues with high expression level of the gene.

The existence of the expression and its level among tissues can be analyzed by a hybridization with radio-labeled DNA fragment (probe) with mRNAs extracted from each tissue immobilized on a sheet (Northern
20 hybridization). It is necessary to obtain a PLA₂ cDNA fragment used as a probe for comparing the quantities in mouse tissues. Such a fragment can be isolated by PCR using primers prepared based on the sequence of EST database and using a cDNA sample originated from mouse tissues as a template. The northern analysis was performed by the obtained cDNA fragment (SEQ ID
25 No.:1). The result indicated clearly that the gene is highly expressed in mouse heart.

(B) Isolation of full length cDNA encoding mouse secretory type PLA₂

For example, upper stream sequence including 5' terminus of the cDNA and down stream sequence including 3' terminus of the cDNA can be obtained by PCR with so called RACE method: Rapid Amplification of cDNA End. Oligomer
5 pairs used in the PCR consist of one PLA₂-specific primer, and the other that corresponds to adapter sequence which is added on the 5' and 3' end of the cDNA. Marathon-ready cDNA (Clontech) originated mouse spleen can be used as a cDNA sample. DNA sequence having mouse secretory type PLA₂ gene and the amino acids sequence encoded by the gene obtained by the method are shown
10 in SEQ ID No.:14 and 15, respectively.

(C) Isolation of full length cDNA encoding human secretory type PLA₂

Generally, it is expected that the same gene have high sequence homology between mouse and human. It is expected that the amino acids
15 residues conserved in PLA₂s originated from various animals (consensus sequence) of which primary structure has been determined are also conserved in the novel PLA₂. Therefore, the cDNA sequence corresponding to the consensus sequence would have high homology with cDNA of human type PLA₂ and this region will be useful for the cloning of human homolog based on the mouse
20 PLA₂ sequence information. Furthermore, the mouse cDNA sequence of this invention has high homology with IIA, IID type. It can be predicted that the human secretory type PLA₂ gene of this invention also has high homology with IIA, IID type. Based on the above assumption, the oligomers were designed by the consensus sequence conserved in these PLA₂ and partial
25 sequence corresponding to human secretory type PLA₂ was cloned by PCR using human genomic DNA (Boehringer Mannheim) as a template. For example, upper stream sequence including 5' terminus of the cDNA and down stream sequence

including 3' terminus of the cDNA can be obtained by PCR with RACE method described above. The oligomer pairs used in the PCR consist of one PLA₂-specific primer, and the other corresponds to adapter sequence which is added on the 5' and 3' end of the cDNA. Or it can be obtained by PCR using human
5 cDNA library as a template based on mouse PLA₂ cDNA sequence which can be expected to have high homology with human counterpart. Marathon-ready cDNA of human small intestine which is expected to express highly was used as a template. DNA sequence having human secretory type PLA₂ gene and the amino acids sequence encoded by the gene obtained by the method are shown in SEQ
10 ID No.:29 and 30, respectively.

Preparation of the protein of this invention

(1) Expression of a recombinant type PLA₂ protein

The protein of this invention can be obtained as a recombinant protein
15 by genetic engineering means (Science, 224, 1431 (1984); Biochem. Biophys. Res. Comm., 130, 692 (1985); Proc. Natl. Acad. Sci., USA., 80, 5990 (1983) etc.). More specifically, a gene encoding a desired protein is inserted into an appropriate vector. A transformant is obtained by incorporating the vector into host cells. A recombinant protein can be obtained by the
20 culture of the transformant.

Both eucaryote and procaryote can be used as host cells. The eucaryote's cells include cells of vertebrate and yeast etc. COS cell (Cell, 23, 175 (1981)) of ape and ovarian cell of a Chinese hamster so on are used as the vertebrate cells.

25 An expression vector which has a promoter located in upper stream of the gene aimed for expression, splice junction of RNA, polyadenylation region and transcription end sequence so on can be used. And the vector may have

a replication origin if it is necessary. As an example for the expression vector is pSV2dhfr (Mol. Cell. Biol., 1, 854 (1981)) having SV40 early promoter etc. As a eucaryotic microorganism, yeast, especially Saccharomyces yeast, is widely used. pAM82(Proc. Natl. Acad. Sci., USA., 80, 1 (1983)) having promoter for acid phosphatase gene etc. can be used as the expression vector for yeast.

As a host of a procaryote, E.coli or Bacillus subtilis are widely used. If these cells are used as a host, it is preferable to use plasmid vector which is replicable in the host and contains a promoter for expression of an objective gene at upper stream of the gene, SD sequence, initiation codon necessary for starting protein synthesis. As a host, E. coli K12 strain etc. is used. As a vector, generally pBR322 and it's derivative are used. It is not limited to these host/vector system. Various kinds of known strains and vectors can also be used. As a promoter, trp promoter, lpp promoter, lac promoter, PL/PR promoter, etc. can be used.

As an insertion method of a desired recombinant DNA into host cell and a transformation method, various general methods are employable. The obtained transformant can be cultured according to general methods and the desired protein can be produced by the culture. As a medium used for the culture, appropriate medium can be selected from various kinds of commonly used medium according to a host cells. For example, the transformant can be prepared by an insertion of the vector comprising human secretory type PLA₂ gene of this invention at down stream of pSVL SV late promoter and the recombinant secretory type PLA₂ protein can be produced by a culture of the transformant at 37°C for 3 days under the existence of 5% CO₂.

The recombinant protein can be separated and purified by various separating procedures utilizing its physical and chemical characteristics,

etc. (Biochemistry, 25(25), 8274 (1986); Eur. J. Biochem., 163, 313 (1987) etc.). For such separating method, extraction by salt, centrifugation, osmotic shock method, ultrasonication, ultrafiltration, gel filtration, various kinds of liquid chromatography such as adsorption chromatography, ion exchange chromatography, affinity chromatography, or high performance liquid chromatography, dialysis, and combination of these method are applicable examples.

(2) Preparation of variant

Amino acid sequence can be changed with deletion/insertion at any position. The methods known as protein engineering can be widely applicable to the substitution of the amino acids sequence. Site-directed deletion method (Nucl. Acids Res., 11, 1645, (1983)), Site-specific mutagenesis method (Zoller, M. J. et al., Methods in Enzymol., 100, 468, (1983), Kunkel, T.A. et al., Methods in Enzymol., 154, 367-382, (1987)), PCR mutation method, method using restriction enzyme and synthesized gene, etc. are the applicable examples.

Using site-specific mutagenesis inducing method described in Sambrook, J. et al., Molecular Cloning: A Laboratory Manual 2nd, No.1-3, Cold Spring Harbor Laboratory Press publication New York (1989) or PCR method as a Site-specific mutagenesis method, mutations can be introduced into the DNA sequence of this invention.

By using appropriate vector and host strain, the DNA sequence mutated by these methods can be expressed with genetic engineering method described such as in Sambrook, J. et al., Molecular Cloning: A Laboratory Manual 2nd, No.1-3, Cold Spring Harbor Laboratory Press publication New York (1989). Several kits such as Mutan TM -SuperExpress Km, Mutan TM -K (Takara shuzo),

Quick Change Site- Directed Mutagenesis Kit (Stratagene) can be used.

Generally, site-specific mutagenesis method can be performed by obtaining a single strand vector including the sequence encoding the protein. Oligo nucleotide primer with desired mutation in the sequence can be produced
5 by general synthesis method, such Crea's method (Crea, R. et al., Proc. Natl. Acsd. Sci. U.S.A., 75, 5765, 1978). Annealing of this primer with the single strand vector having this DNA sequence is performed, then reaction with DNA polymerase such as E. coli polymerase I Klenow fragment is followed to complete the synthesis of the mutated strand. Hetero double strands
10 comprising one strand encoding non-mutation sequence and another strand having desired mutation are formed. Appropriate bacteria or cells are transformed by this double strand vector. The clone is selected by hybridization of radioactivity probe consisted of ^{32}P -labeled mutated sequence-including primer (Wallace, R.B., Nucleic Acids Res., 9, 3647, 1981).
15 Selected clone contains the recombinant vector having mutated sequence. After the selection of such clone, the region encoding mutated protein can be inserted into an expression vector for transformation.

Hereafter, variants can be produced by the host cells according to the preparation method of the recombinant protein shown in (1).

20

Determination of secretory type PLA₂ activities

The determination of PLA₂ activities of the recombinants and the variants obtained above was carried out by the following method.

- ① React the culture products containing recombinant secretory type PLA₂
25 protein or the control culture products containing no recombinant secretory type PLA₂ protein with ^3H -oleic acid-labeled E. coli membrane phospholipid fractions.

- ② Determine the quantity of released ^3H -oleic acid according to Elsbach's method (Methods Enzymol., 197, 24-31 (1991)).
- ③ Certify the existence of PLA_2 activity by comparing the quantity of ^3H -oleic acid.

5

Preparation of antibody against the protein of this invention

The antibody against the protein of this invention can be produced by the following methods.

(1) Preparation of polyclonal antibody

10 Peptides synthesized by a usual peptide synthesizer based on a part of the deduced amino acids sequence are used as immunogen. Alternatively, protein produced by bacteria, yeast, insect cells and mammalian cells, which are transformed by the expressing vector encoding the protein into, can be purified by general protein chemical method and also used as immunogen.

15 Thus, the polyclonal antibody that specifically recognizes the protein can be easily prepared and purified. Using this immunogen, animals are immunized according to the appropriate method described in Antibodies; A Laboratory Manual, Lane, H.D. et al., Cold Spring Harbor Laboratory Press publication New York 1989. For example, polyclonal antibody is prepared

20 from the serum of the immunized animals, such as mouse, rat, hamster, and rabbit.

(2) Monoclonal antibody

 Lymphocytes are isolated from spleen or lymph node of the immunized mouse or rat with the immunogen as described above. Hybridomas are prepared

25 by fusion of the isolated lymphocyte and myeloma cells according to Kohler and Milstein's method (Nature, 256, 495-497(1975)). Monoclonal antibody can be produced from the hybridoma. For example, the monoclonal antibody

against the protein of this invention can be obtained by the following steps:

- (a) Immunization of mice by the protein,
- (b) Isolation of immunized mouse spleen and separation of the spleen cells,
- 5 (c) Fusion of separated spleen cells and mouse myeloma cells in the presence of fusion-promoting agent, such as polyethylene glycol, according to Kohler's method described above,
- (d) Culture of hybridoma cells obtained from selective medium in which unfused myeloma cells can not grow,
- 10 (e) Selection of hybridoma cells that produce the desired antibody by the evaluation with enzyme-linked immunosorbent assay (ELISA), and western blot, and cloning them by the limited-dilution method etc.,
- (f) Culture of the hybridoma cells that produce the monoclonal antibody and collection of the monoclonal antibody.

15

Assay kit for secretory type PLA₂ and Diagnostic reagent for secretory type PLA₂ relating disease

In this invention, the protein of this invention can be assayed by using the monoclonal antibody against the protein. Any kind of assay using the antibody against the protein of this invention is applicable, if the assay
20 determines the quantity of antibody corresponding to the antigen quantity (ex. Quantity of the protein of this invention) in the assay solution, or the quantity of antibody-antigen complex by the chemical or physical methods, and calculates them by the standard curve prepared by using the standard
25 solution containing a known quantity of the antigen. For examples, nephelometry, competition method, immunometric assay, and sandwich method can be adapted.

For the immobilization of the antigen or the antibody, the chemical binding generally useful for immobilization of the protein or enzyme can be used. As a carrier, insoluble polysaccharides such as agarose, dextran, or cellulose, or synthetic resins such as polystyrene, polyacrylamide, 5 silicon, or glass are given for examples.

In the sandwich method, the quantity of the protein in assay solution can be determined by the following steps.

(1) React the immobilized antibody of this invention with the assay solution, then react them with another labeled-antibody of this 10 invention.

(2) Determine the activity of the labeling agent on the immobilized carrier.

There is no need that the immobilized antibody is the same as the labeled antibody. For example, if the immobilized antibody recognizes the N- 15 terminus of the protein, the labeled-antibody that recognizes C-terminus of the protein can be used.

Radioisotope, enzyme, and fluorescent substance can be used as a labeling agent. As a radioisotope, ^{125}I , ^3H , ^{14}C etc. can be used. As an enzyme, peroxydase, β -galactosidase, β -glucosidase, alkaline phosphatase, 20 etc., can be used.

By using these assay, if the concentration of the protein is excess, it is possible to diagnose or diagnose patients with the diseases such as septic shock, adult respiratory distress syndrome, pancreatitis, external injuries, bronchial asthma, allergic rhinitis, rheumatoid arthritis, etc.

25 Therefore, the antibody of this invention provides "Diagnostic reagent" and "Assay kit" which can be useful in the diagnosis of these diseases.

Screening method for a compound that specifically inhibits PLA₂ activity

As a "Screening method" of this invention, high through put screening with the protein of this invention is given for example. For example, samples, phospholipid substrate (racemic diheptanoyl thio-phosphatidylcholine) and color-developing reagent (5,5'-dithiobis (2-nitrobenzoic acid)) are added into 96-well plate according to the Reynolds's method (Anal. Biochem. 204, 190-197(1992)). After the addition of the protein, the wells were incubated at 40°C for the appropriate time, and the change of absorbance (OD at 405 nm) is measured. The inhibiting activity of the sample for this secretory type PLA₂ can be evaluated by comparing with the value obtained in the absence of the sample.

Compound obtained from the screening method

Secretory type PLA₂ is involved in the release of fatty acids (ex. arachidonic acid). Excess release of fatty acid causes various diseases such as septic shock, adult respiratory distress syndrome, pancreatitis, external injuries, bronchial asthma, allergic rhinitis, rheumatoid arthritis. The compound obtained from the screening method inhibits the activity of secretory type PLA₂. Therefore, the compound is useful for the therapy of diseases including septic shock in which the excess production of secretory type PLA₂ is involved.

The compound includes pharmaceutically acceptable salts. The salt is prepared by well-known methods. Non-toxicity alkaline metal salt, such as sodium, potassium, lithium, calcium, magnesium, and barium, alkali earth metal salt, and ammonium salt, etc. are included.

A pharmaceutical preparation is made with a pharmacologically

effective quantity of the compound as an active ingredient. As a medication unit form of the pharmaceutical preparation, various kinds of form can be selected according to an object of therapy. As a solid dosage form, tablet, pill, powder, epipastic, granule, capsule, etc. are included. And as a liquid dosage form, solution, suspension, emulsion, syrupus, elixir, etc. are included. These are classified into oral agent, non-oral agent, nasal agent, vaginal agent, suppository, sublingual agent, ointment, etc. according to the dosage route. Preparation and molding can be performed according to the general methods.

The dosage forms of the pharmaceutical preparation as described above are not limited and these are determined according to each preparation form, age of subjects, sex, state of a disease or other condition. For example, tablet, pill, granule, capsule, solution, suspension, and emulsion are given through oral. An injection agent is used by itself or as the mixture with a general fluid replacement such as dextrose or amino acids, and given through vein. Moreover, injection is given into muscle, skin, abdominal cavity or under skin, if necessary.

The effective quantity of the invention compound should be comprised in the pharmaceutical preparation as mentioned above and its dosage is not limited. It is chosen according to the effect of desired therapy, the dosage method, the duration of therapy, the age of subject, sex, and the other conditions. Generally, the dosage is about 1 – 10 mg per 1 kg body weight a day. The preparations can be given in one to several divisions per day.

The antibody of this invention inhibits the PLA₂ activity of the secretory type PLA₂ of this invention via the specific binding to PLA₂ of this invention. Therefore, the antibody of this invention, as well as the compound obtained from the screening method of this invention, are useful

for the therapy of diseases, such as septic shock, in which excess production of secretory type PLA₂ is involved.

Example

5 The invention is explained in more detail by the following examples.

General experiment protocols used in each step in this invention follow Current Protocols in Microcular Biology (F. M. Ausubel et al. Ed., John Wiley & Sons. Inc.). DNA oligomers were purchased from International Reagents Corp. (Kobe, Japan). Data analysis was performed with GENETYX-SV/RC of
10 Software Development Inc. (Japan). Determination of DNA sequences was routinely performed with several clones in order to eliminate the effects of misincorporation that might be caused in the PCR reactions .

cDNA fragment that can encode the PLA₂ detected in EST database is shown as SEQ ID No.:1 at Sequence Listing. This sequence is a fragment. It is
15 required to isolate the undetected cDNAs connected with 5' terminus and 3' terminus of the fragment and to reconfirm the fragment sequence at the same time for the analysis of the fragment-originated gene itself and the function of the protein encoded by the gene. For the cloning the full length cDNA, it is favorable to use the tissues in which the gene is highly expressed.
20 In order to compare the quantities of the gene expression levels among the mouse tissues by Northern analysis, it is required to obtain a PLA₂ cDNA fragment available for the probe. Such PLA₂ cDNA fragment can be isolated by PCR using cDNA samples derived from mouse tissues as templates.

25 Example 1 Isolation of a cDNA fragment of a novel mouse PLA₂

Short DNA oligomers shown in SEQ ID No.:2 to 5 were prepared based on the DNA sequence shown in SEQ ID No.:1. A relative positioning of these

DNA oligomers are shown in Fig.1. 319 base pairs of PLA₂ cDNA fragments could be amplified by PCR using the oligomer pair of SEQ ID No.:2 and 3, and 315 base pairs of PLA₂ cDNA fragments could be amplified by PCR using oligomers of the SEQ ID No.:4 and 5. If PCR was performed by using oligomers of SEQ ID No.2 and 3 at first, then amplified products were used as templates at second PCR with oligomers of SEQ ID No.4 and 5, it was expected that PLA₂ cDNA could be amplified with higher specificity and sensitivity (Nested-PCR).

cDNA samples were prepared from reverse transcription of mRNA extracted from mouse tissues (brain, heart, kidney, spleen, stomach, etc.) of 129/Svj strain. Using these cDNA samples as templates, PCR was performed using oligomers of SEQ ID No.:2 and 3. TaKaRa Ex Taq (Takara Shuzo, Japan) was used as an enzyme, and composition for PCR reaction was followed to the instruction of the enzyme. As an amplification device, Thermal Cycler (Perkin Elmer Cetus) was used. The amplification was performed at 94°C for 1 min, 55°C for 1 min, and 72°C for 1 min for 30 cycles. After the reaction was completed, second PCR was performed using 1 µl of the reaction solution as template with oligomers of SEQ ID No.:4 and 5. The reaction condition was same as the first PCR. The solution of the PCR reaction was applied to 1.2% agarose gel electrophoresis and the amplified products were separated. The DNA of the expected size was amplified from the cDNA originated with all tissues.

The DNA was cut out from the gel. Purification of DNA was performed using GenElute Agarose spin column (Spelco). The DNA was ligated with pCRII vector (Invitrogen), and E. coli DH 5α strain (Toyobo) was transformed with the ligation solution. The obtained recombinant E. coli was cultured, and plasmid DNA was prepared by GFX Micro Plasmid Prep Kit (Pharmacia Biotech).

The sequence inserted into the vector was determined with PRISM 310 Genetic Analyzer (PE Applied Biosystems). The result indicated that the DNA consisted of the sequence corresponding to SEQ ID No.:1 was amplified by the PCR.

5

Example 2 Analysis of expression pattern of the secretory type PLA₂ mRNA in each mouse tissue

The existence and its level of the expression in tissues can be analyzed by a hybridization with radio-labeled DNA fragment (probe) with mRNAs extracted from each tissue immobilized on a sheet (Northern hybridization). The purified DNA fragment after the PCR amplification was labeled with Megaprime DNA labling sysytem (Amersham Pharmacia Biotech). Using this fragment as a probe, the hybridization was performed with mouse Multiple tissue northern blot (Clontech). Autoradiography was performed after the washing with the solution containing appropriate concentration of salt. The result indicated that the PLA₂ mRNA was highly expressed in heart among the tissues examined.

Example 3 Determination of cDNA primary construction of mouse secretory type PLA₂

Up stream including 5' terminus and down stream including 3' terminus of the cDNA can be isolated by the following method utilizing the information of known portion (central part) of the cDNA. Several antisense oligomers and sense oligomers are prepared according to the known sequence. cDNA including unidentified part can be amplified using cDNA samples which has attached adapter DNAs at the end of cDNA. Oligomer pairs consisted of a oligomer corresponding to the adapter-specific sequence and a PLA₂ specific

oligomer are used (RACE method).

Mouse spleen Marathon-ready cDNA (Clontech) was used as a cDNA sample. Oligomers used for the RACE method were shown in SEQ ID NO.:6 to 9. Among them, SEQ ID No.:6 and 7 are antisense oligomers for isolating 5' up stream, and SEQ ID No.:8 and 9 are sense oligomers for isolating down stream.

RACE method was performed by Nested PCR as same as PCR amplification of the central portion. For 5' side RACE, the oligomer of SEQ ID No.:6 and oligomer AP-1 attached with RACE kit (Clontech) were used at the first RACE, and the oligomer of SEQ ID No.:7 and oligomer AP-2 (Clontech) were used at the second RACE. For 3' side RACE, the oligomer of SEQ ID No.:8 and AP-1 were used at the first RACE, and the oligomer of SEQ ID No.:9 and AP-2 were used at the second RACE. TaKaRa Ex Taq (Takara Shuzo, Japan) was used as an enzyme. The first amplification was performed at 94°C for 1 min, 60°C for 1 min, and 72°C for 2 min for 30 cycles, the second amplification was performed at 94°C, for 1 min, 62°C for 1 min, and 72°C for 2 min for 30 cycles. After the PCR, the amplified products were separated by electrophoresis. A band of about 450 base pair was detected by 5'RACE and a band about 470 base pair was also detected by 3' RACE. The cloning of these DNAs were performed as the same way of Example 1 and the sequences were determined by PRISM 310 Genetic Analyzer (PE Applied biosystems).

Three parts of PLA₂ cDNA were isolated separately. Those are upper region, central part, and down-stream region. To confirm that these cDNAs are derived from one integral gene, oligomers shown at from SEQ ID NO.:10 to 13 were prepared and the PCR was performed using Marathon-ready cDNA (Mouse spleen, Clontech) as a template with oligomers shown at SEQ ID NO.:10 and 12. The second PCR was performed using 1 µl of the reaction solution as template with oligomers of SEQ ID No.:11 and 13 after the reaction. TaKaRa

Ex Tag (Takara) was used as an enzyme for the each PCR. The amplification was performed at 94°C for 1 min, 60°C for 1 min, 72°C for 4 min for 30 cycles. The amplified DNA was cloned as same as described above, and the sequence was determined. The determined cDNA sequence is shown at SEQ ID No.:14 and
5 the amino acids sequence encoded by the cDNA is shown at SEQ ID No.:15.

From the length of the cDNA encoding the protein, it is clear that the number of amino acid residues of the PLA₂ protein is 142. This protein possesses all structural features (central part for PLA₂ activity, sequence of Ca²⁺ binding part, number of Cys residues) conserved among the secretory
10 type PLA₂ family molecules. However, this protein consists of a different sequence from any of known secretory type PLA₂s, and homology at the amino acids level are 35.8% with mouse IB type, 47.7% with mouse IIA type, 38.0% with mouse IIC type, 41.8% with mouse IID type, 41.0% with mouse V type, and 35.8% with mouse X Type, respectively.

15

Example 4 Determination of cDNA primary construction of human secretory type PLA₂

Generally, it can be expected that the same type gene of mouse and human have high sequence homology each other. It was considered that the cDNA
20 sequence corresponding to the consensus sequence in mouse cDNA sequence would have high homology to human PLA₂ and this region is useful for the cloning of human homolog based on the mouse PLA₂ gene information. It was proved that the mouse cDNA sequence determined at Example 3 has high homology to IIA type and IID type. Therefore, it was expected that the human secretory
25 type PLA₂ gene corresponding to the mouse PLA₂ gene would have high homology to human IIA type and human IID type. Two oligomers were designed on basis of the mouse cDNA sequence, consensus sequence of human IIA type and human

IID type.

An oligomer (Sense oligomer) of SEQ ID No.:16 was prepared on the basis of cDNA sequences corresponding to 23rd Tyr to 28th Gly shown in SEQ ID No.:14 with the consideration of cDNAs corresponding to human IIA type and human IID type. And other oligomer (Antisense oligomer) of SEQ ID No.:17 were also prepared on the basis of cDNA sequence corresponding to 46th His to 52nd Arg shown in SEQ ID No.:14. The IIA type like human PLA₂ gene including IIA type was isolated with high sensitivity and high specificity by PCR using these oligomers from human Genomic DNA. Using Human Genomic DNA of Boehringer Mannheim as templates, PCR was performed at 94°C for 1 min, at 50°C for 1 min, at 72°C for 2 min for 30 cycles and the other condition was as same as Example 1. Three types-amplified products consisting of about 800, 350, and 300 base pairs were detected after the electrophoresis.

These fragments were cloned as same as Example 1 and the sequence of the fragments were determined. From the results, it became clear that the DNA fragment of about 800 base pairs is human IIA type PLA₂ and the DNA fragment of about 350 base pairs is human IID type PLA₂. These fragments have an intron sequence at the same position. Therefore, it was expected that novel PLA₂ would have an intron at the same position. The DNA fragment of about 300 base pairs is shown in SEQ ID No.:18. This base sequence contains a 212 base pairs sequence (from 58th to 269th of SEQ ID no.:18) expected to be an intron at the same position of IIA type and IID type. Homology of the sequence expected to be an exon is 85.1% with the corresponding mouse cDNA region determined at Example 3. Thus, it can be expected that this fragment is a part of a novel human PLA₂ gene.

Based on the obtained base sequence, three sense oligomers and three

antisense oligomers were designed. These oligomers are shown in SEQ ID No.:19 to 24.

For detecting tissues with high expression level of the gene, Nested-PCR was performed as the same way of Example 1 by using these oligomers and human cDNA originated from various tissues as templates. First PCR was performed by using oligomers of SEQ ID No.:19 and 22. Second PCR was performed by using the amplified products as template with oligomers of SEQ ID No.:20 and 23. Both the first and the second PCR were performed at 94°C for 1 min, at 55°C for 1 min, at 72°C for 1 min for 30 cycles and the other condition was as same as Example 1. Marathon-ready cDNA (Human kidney, pancreas, small intestine, spleen, lung, heart, leukocyte, liver) were used as templates. From the result, it was expected that small intestine is a tissue with high expression level of the gene. The obtained fragment was cloned as same as Example 1 and the base sequence was determined. From the result, it became clear that the cDNA sequence consist of the expected exon region.

The upper stream including 5' terminus was isolated by RACE method. The experiment was conducted on the condition described in Example 3 and Marathon-ready PCR cDNA (Human spleen, Clontech) was used as a template. SEQ ID No.:23 and 24 were used for antisense oligomer for isolating upper stream. After the RACE, DNA fragments of about 120 base pairs was obtained and the sequence was determined. Two antisense oligomers (SEQ ID No.:25 and 26) were designed for isolating further upper stream and RACE was performed as the same way. After the RACE, DNA fragment of about 150 base pairs was obtained and the sequence was determined.

The down stream including 3' terminus was isolated by the following Nested-PCR. It has become clear that the homology of novel human PLA2 is

very high with the corresponding mouse PLA2 from the obtained base sequence. Based on the mouse cDNA sequence (SEQ ID No.:14) determined Example 3, two antisense oligomers (SEQ ID No.:27 and 28) corresponding to 595th – 615th and 601st – 621st of the sequence were prepared. PCR was performed by using these oligomers as antisense primers. First PCR was performed by using oligomers of SEQ ID No.:20 and 28. Second PCR was performed by using the amplified products as template with oligomers of SEQ ID No.:21 and 27. Both the first and the second PCR were performed at 94°C for 1 min, at 55°C for 1 min, at 72°C for 2 min for 30 cycles and the other condition was as same as Example 1. Marathon-ready cDNA (Human small intestine, Clontech) was used as a template. From the PCR, DNA fragment of about 300 base pairs was obtained and the base sequence was determined as same as Example 1.

The central part, the two upper streams, and the two down streams of the PLA2 cDNA were partially isolated at the above steps. These sequences have continuity and the connected sequence is shown at SEQ ID No.:29.

From the length of the cDNA encoding the protein, the number of amino acid residues of the PLA₂ protein is 142. This protein (SEQ ID No.:30) conserves all structural features (central part of PLA₂ activity, sequence for Ca²⁺ binding part, and number of Cys residues) conserved among secretory type PLA₂ family molecules. However, this protein consists of a different sequence from any of known secretory type PLA₂s, and homology of the amino acids sequence is 39.0% with human IB type, 51.4% with human IIA type, 39.2% with human IID type, 45.7% with human V type, and 38.2% with human X type.

25 Example 5 Expression of the recombinant PLA₂ protein

Nested-PCR was performed by using the oligomers(SEQ ID No.:31 – 34) which were prepared on the basis of the obtained cDNA sequence, and the cDNA

sequence encoding the region of the amino acids (the coding region) was amplified. SEQ ID No. 31 and 33 were used for the first PCR. SEQ ID No.:32 and 34 were used for the second PCR. Marathon-ready PCR cDNA (Human Small Intestine) of Clontech was used as a template. The oligomer shown in SEQ ID No.:32 has a sequence recognized by the restriction enzyme NotI and a sequence (Kozak sequence) that promotes the transcription from mRNA to protein. The oligomers shown in SEQ ID No.:34 has a sequence recognized by the restriction enzyme XbaI. There is no sequence recognized by the restriction enzyme NotI or XbaI within the coding region. Therefore, after the digestion of PCR-amplified cDNA fragments with these restriction enzymes, the cDNA corresponding to the coding region can be prepared. It has the Kozak sequence at upper stream of the transcription starting point and the cutting edges of NotI or XbaI on the upper terminus and the down stream terminus of the cDNA, respectively.

The PLA₂ expressing vector was prepared by insertion of this cDNA into pcDNA 3.1(+) (Invitrogen) at the down stream of its promoter in the right direction (the sites between NotI and XbaI sites). The base sequence from the promoter to PLA₂ cDNA was determined again to confirm the absence of artificial mutation. Then, the PLA₂ expressing vector was inserted into COS-7 cells, the established cell line originated from monkey kidney. Transfection was performed with FuGENE™6 transfection reagent (Boehringer Mannheim) according to the method of the manufacture's instruction. At three days after the transfection, PLA₂ activities in the culture supernatant and the cell lysates were measured. Measurement of PLA₂ activities was carried out according to the Elsbach et al.'s method (Methods Enzymol. 197, 24-31 (1991)) using 3H-oleate-labeled E. coli membrane phospholipid fractions as the substrate. Significantly high PLA₂ activities were

detected in the culture supernatant compared with the supernatant in the cultured cells in which a control plasmid with no cDNA of the PLA₂ were transfected (Fig.2). In addition, high concentration of Ca²⁺ was required for the exertion of the enzymatic activities (Fig. 3).

5

Example 6 Screening for a compound that inhibits PLA₂ activity

Inhibitory activity against this novel type of human secretory type PLA₂ was determined with Indoxam that is a 1-oxamoylindolidine derivative. It has already been reported that Indoxam inhibits the enzymatic activities of IIA type and IB type secretory type PLA₂ (Yokota et al., Biochim. Biophys. Acta (1999) 1438, 213-222). The PLA₂ activities were determined by the measurement of the quantity of released ¹⁴C-oleic acid from ¹⁴C-labeled 1-palmitoyl-2-oleoyl-phosphatidylcholine (POPC), according to the Draheim et al.'s method (J. Med. Chem., (1996) 39, 5159-5175). In the solution composed of 50 mM Tris-HCl (pH 8.0), 200 mM NaCl, 2 mM CaCl₂, and 1 mg/ml bovine serum albumin, the substrates composed of 1 mM POPC (the mixture of about 100,000 cpm ¹⁴C-POPC and unlabeled POPC) and 3 mM deoxycholic acid were incubated with each secretory PLA₂ in the presence of various concentrations of Indoxam at 40°C for 60 min. Then, the quantity of released ¹⁴C-oleic acid was measured. Purified materials were used in the case with human IB type (2 ng), IIA type (10 ng) and X type (4 ng). Human V type, IID type and the secretory type PLA₂ of this invention (IIE type) were prepared from the culture supernatant of CHO cells that stably express them.

The quantity of released ¹⁴C-oleic acid from ¹⁴C-POPC by each human secretory type PLA₂ in the absence of Indoxam was regarded as 100% and the quantity of released ¹⁴C-oleic acid in the presence of each concentration of Indoxam was shown as %. As the result, it was conformed that Indoxam

strongly inhibits the enzymatic activities of human PLA₂ of this invention (IIE type), IID type and IIA type (Fig. 4)

Industrial Applicability

5 This invention provides human secretory type PLA₂; a DNA encoding human secretory type PLA₂; a vector including the DNA; a transformant having the vector; a method for producing human secretory type PLA₂ using the transformant.

10 An analytic mean for this secretory type PLA₂-related diseases and a screening mean for a specific inhibitory compound against this enzyme are provided by using the secretory type PLA₂ of this invention. An assay using an antibody for the enzyme can be applied to the diagnosis of various diseases.
